

7. Deep Learning model performance (iteration 2); discussion of what went wrong and how to fix it

Deep Learning model is underperforming when compared to baseline model when looking at MSE. In order to improve this, we are reviewing the model architecture and considering different new options.

Running out of computing power when processing the data. We are considering different kinds of ways to cluster the data.

- **Discuss how your strategy changed from last week based on the results Examples: Did you move to a different model architecture because you were overfitting? Did you add data transformation steps to your preprocessing pipeline?**

We re-did the clustering of households taking into account data leakage. In particular, we made sure that the testing part of the data is excluded while performing clustering.

- **Put your preprocessed data through the revised deep learning model architecture.**

- **List the performance metrics and any useful diagnostic figures**

We use MSE and MAE as the metric to measure how well the model's prediction mimics the actual load usage.

- **Describe where the model worked well and where it didn't work well**

Computing time when clustering data points is no longer an issue.
